Abstract

A new class of spherical codes called wrapped spherical codes is constructed by "wrapping" any sphere packing \( \Lambda \) in Euclidean space onto a finite subset of the unit sphere in one higher dimension. The mapping preserves much of the structure of \( \Lambda \), and unlike previously proposed maps, the density of wrapped spherical codes approaches the density of \( \Lambda \), as the minimum distance approaches zero. In particular, wrapped spherical codes are asymptotically optimal as the minimum distance shrinks, whenever the packing \( \Lambda \) is optimal. Additionally, wrapped spherical codes can be effectively decoded using a decoding algorithm for \( \Lambda \).

1 Introduction

A \( k \)-dimensional spherical code is a set of points in \( \mathbb{R}^k \) that lie on the surface of a \( k \)-dimensional unit radius sphere. See [1, 2] for applications of spherical codes. In this paper we concentrate on the generic spherical code design problem (with respect to minimum distance), rather than a particular application of spherical codes.

Denote the surface of the unit radius \( k \)-dimensional Euclidean sphere by

\[
S_k \equiv \{ (x_1, \ldots, x_k) \in \mathbb{R}^k : \sum_{i=1}^{k} x_i^2 = 1 \},
\]

(1)

the \((k-1)\)-dimensional content (surface area) of \( S_k \) by \( A_k = \frac{\kappa_k}{\Gamma\left(\frac{3}{2}+1\right)} \), and the \( k \)-dimensional content (volume) of \( S_k \) by \( V_k = \frac{\pi^{k/2}}{\Gamma\left(\frac{k}{2}+1\right)} \), where \( \Gamma \) is the usual gamma function defined by \( \Gamma(x) = \int_0^\infty e^{-t} t^{x-1} \, dt \). The minimum distance of a \( k \)-dimensional spherical code \( C \subset S_k \) is defined as

\[
d \equiv \min_{X,Y \in C} \|X - Y\|,
\]

(2)

where \( \|X - Y\| \) is the Euclidean distance in \( \mathbb{R}^k \) between codepoints \( X \) and \( Y \). The minimum distance of a spherical code is directly related to the "quality" of the code in many channel coding applications. For channel codes, one generally desires to maximize the minimum distance for a given number of codepoints.

As this paper concentrates on asymptotically small \( d \), it is important to clarify some notation. For functions \( f \) and \( g \), we use the notation \( \mathcal{O}(g(d)) \) to mean that there exist positive constants \( c \) and \( d_0 \) such that \( 0 \leq f(d) \leq cg(d) \) for all \( d \in (0, d_0) \). The dimension \( k \) shall be regarded as a constant in the asymptotic analysis.

The angular separation between two points \( X, Y \in S_k \) is \( \cos^{-1}(X \cdot Y) \). The minimum angular separation of spherical code \( C \) is defined as

\[
\theta \equiv 2 \sin^{-1}\left(\frac{d}{2}\right),
\]

(3)

\[
= d + \frac{d^2}{24} + \mathcal{O}(d^3).
\]

(4)

The set of points on \( S_k \) whose angular separation from a fixed point \( X \in S_k \) is less than \( \phi \) is called a spherical cap centered at \( X \) with angular radius \( \phi \) and is denoted by

\[
c_X(k, \phi) \equiv \{ Y \in S_k : X \cdot Y > \cos \phi \}.
\]

(5)

When the center \( X \) of a spherical cap is not relevant, the notation may be abbreviated as \( c(k, \phi) \). If two spherical caps of angular radius \( \theta/2 \) are centered at different codepoints of a spherical code with minimum distance \( d \) and minimum angular separation \( \theta \), then the caps are disjoint. The \((k-1)\)-dimensional content of \( c(k, \theta/2) \) is denoted by \( A(c(k, \theta/2)) \).

A sphere packing (or simply packing) is a set of mutually disjoint, equal radius, open spheres. The packing radius is the radius of the spheres in a packing. As defined in [3], "A packing is said to have density \( \Delta \) if the ratio of the volume of the part of a cube covered by the spheres of the packing to the volume of the whole cube tends to the limit \( \Delta \), as the side of the cube tends to infinity." The density \( \Delta_C \) of a spherical code \( C \subset S_k \) with minimum distance \( d \) is the ratio of the total \((k-1)\)-dimensional content of \( |C| \) disjoint spherical caps centered at the codepoints and with angular radius \( \theta/2 \), to the \((k-1)\)-dimensional content of \( S_k \); that is, \( \Delta_C = |C| \cdot A(c(k, \theta/2))/V_k \). Let \( M(k, d) \) be the maximum cardinality of a \( k \)-dimensional spherical code with minimum distance \( d \), and let \( \Delta(k,d) \) be the maximum density among all \( k \)-dimensional spherical codes with minimum distance \( d \). Then,

\[
\Delta(k, d) \equiv \frac{M(k,d)A(c(k, \theta/2))}{A_k}.
\]

The value of $M(k,d)$ is easy to compute for all $d$ when $k = 2$. However, $M(k,d)$ is unknown for all $k \geq 3$ except for a handful of values of $d$, although a number of bounds have been given [4–11]. For asymptotically small $d$, the tightest known upper bounds on $M(k,d)$ are given in [7] for $k = 3$ and in [4] for $k \geq 4$, and code constructions in [10, 12, 13] provide the tightest known lower bound. However, in several dimensions, there exists a nonvanishing gap between these upper and lower bounds as $d \to 0$.

A family of codes $\{C(k,d)\}$ is asymptotically optimal if $|C(k,d)|/M(k,d) \to 1$ as $d \to 0$, or equivalently, if $\Delta C(k,d)/\Delta(k,d) \to 1$ as $d \to 0$. It has been shown that $\lim_{d \to 0} \Delta C(k,d)$ is equal to the density of the densest $(k-1)$-dimensional sphere packing in [1]. This gives packing, we show that this limit can always be achieved using our construction. Hence, given a densest packing in $\mathbb{R}^{k-1}$, we construct optimally optimal spherical codes. Figure 1 shows bounds on the asymptotic densities of the best spherical codes for up to 49 dimensions.

2 Known lower bound constructions

Any known $k$-dimensional spherical code with minimum distance $d$ gives a lower bound on $M(k,d)$, and hence on $\Delta(k,d)$. Much work has been done to find the best spherical codes, such as from binary codes [14], shells of lattices [15], permutations of a set of initial vectors [16], simulated annealing or repulsion-energy methods [10, 17], concatenations of lower dimensional codes [11], projections of lower dimensional objects [6, 8, 10], and other means [18, 19]. For more comprehensive references, see [1, 2].

Unfortunately, none of the spherical coding methods above performs well in a fixed dimension $k$, as $d \to 0$. Also, many of the methods above produce spherical codes for only a finite number of minimum distances $d$. Recent developments have shown that it is possible to obtain optimally optimal $k$-dimensional spherical codes whenever the laminated lattice is the densest $(k-1)$-dimensional sphere packing [2, 12, 13]. This paper improves upon this result by providing a construction method which directly maps any $(k-1)$-dimensional packing onto a finite subset of $S_k$. It also allows efficient decoding to be performed by using a few simple operations in conjunction with the best decoding algorithm for the underlying packing.

3 Wrapped spherical codes

Any spherical code can be described by the projection of its codepoints to the interior of a sphere of one less dimension via the mapping $(x_1, \ldots, x_{k-1}, \sqrt{1 - \sum_{i=1}^{k-1} x_i^2}) \to (x_1, \ldots, x_{k-1})$. Conversely, a $k$-dimensional spherical code may be obtained by placing codepoints within $S_{k-1}$ and projecting each codepoint onto $S_k$ using the reverse mapping. This simple mapping was used by Yaglom [6] to map a $(k-1)$-dimensional lattice $\Lambda$ onto $S_k$. However, the distortion created by mapping $\Lambda$ to $S_k$ gives poor asymptotic spherical code densities, even if $\Lambda$ is the densest lattice in $k-1$ dimensions, as summarized in Figure 1. This is due to the "warping" effect on the codepoints near the boundary.

In this section we introduce a new mapping which results in less distortion of the original lattice. The mapping effectively "wraps" any packing in $\mathbb{R}^{k-1}$ around $S_k$ (actually into a finite subset of $S_k$), and hence we refer to the spherical codes it constructs as wrapped spherical codes. This technique creates codes of any size and thus provides a lower bound on achievable minimum distance as a function of code size. We shall show that the spherical code density approaches the density of the underlying packing, as $d \to 0$.

3.1 Construction of wrapped spherical codes

Let $\Lambda$ be a sphere packing in $\mathbb{R}^{k-1}$ with minimum distance $d$ and density $\Delta \Lambda$. $\Lambda$ may be either a lattice packing or a nonlattice packing. Let $0 = \xi_0 < \cdots < \xi_N = 1$, and for $x \in [0,1]$, let $\xi(x) \equiv \max\{\xi_i : \xi_i \leq x\}$ and $\hat{\xi}(x) \equiv \min\{\xi_i : \xi_i > x\}$. The real numbers $\xi_0, \ldots, \xi_N$ are referred to as latitudes and will be chosen later to yield a large code size. The ith annulus is defined as the set of points $(x_1, \ldots, x_k) \in S_k$ that satisfy $\xi_i \leq x_k < \xi_{i+1}$ (i.e., points between consecutive latitudes). Define the many-to-one function $f' : S_k \to \mathbb{R}^{k-1}$ by

$$f'(x_1, \ldots, x_k) = g(x_k) \cdot \frac{(x_1, \ldots, x_{k-1})}{\sqrt{1 - x_k^2}},$$

where

$$g(x) = \sqrt{1 - \hat{\xi}(x)^2 - \sqrt{(x - \hat{\xi}(x))^2 + (1 - \hat{\xi}(x)^2 - \sqrt{1 - x^2})^2}},$$

and $(x)_+ = \max\{0, x\}$. If $X = (x_1, \ldots, x_k)$ and $Y = \mathbf{f}'(X) \neq 0$, then

$$\sqrt{1 - \hat{\xi}(x_k)^2} - ||Y|| = \left(\sqrt{1 - \hat{\xi}(x_k)^2}, \xi(x_k)\right) - \left(\sqrt{1 - x_k^2}, |x_k|\right),$$

which is shown geometrically in Figure 2. Define the buffer region as the set

$$B' = \left\{(x_1, \ldots, x_k) \in S_k : (|x_k| - \hat{\xi}(x_k))^2 + \left(\sqrt{1 - \hat{\xi}(x_k)^2} - \sqrt{1 - x_k^2}\right)^2 < d^2\right\}.$$

A useful spherical code with respect to $\Lambda$ is defined by $C^\Lambda = \{f'^{-1}(\Lambda \setminus \{0\})\} \setminus B'$. Figure 3 illustrates this three
Figure 1: Comparison of the asymptotic density of various spherical codes versus the density of wrapped spherical codes. The wrapped codes were constructed with respect to the densest known packing in each dimension.

Figure 2: (a) Geometrical interpretation of $f(X)$. (b) Annuli.
Lemma 1 For every $Y \in \mathbb{R}^{k-1} \setminus \{0\}$,

$$(f')^{-1}(Y') = \left\{ \frac{g_i Y}{||Y'||} : 0 \leq h_i < \sqrt{(\xi_{i+1} - \xi_i)^2 + \left(\sqrt{1 - \xi_i^2} - \sqrt{1 - \xi_{i+1}^2}\right)^2} \right\},$$

where $h_i = \sqrt{1 - \xi_i^2} - ||Y'||$ and $g_i = \left(1 - \frac{\xi_i^2}{h_i^2}\right)\sqrt{1 - \xi_i^2} - \frac{h_i^2}{h_i} \cdot \sqrt{4 - h_i^2}$.

Proof: Omitted.

Lemma 1 also allows $f^{-1}$ to be calculated, via

$$f^{-1}(Y) = \left\{ (x_1, \ldots, x_k) \in (f')^{-1}(Y) : x_k \leq 1/\sqrt{2} \right\} \cup \left\{ (x_1, \ldots, x_k) : x_k > 1/\sqrt{2} \right\}.$$

The image under $f'$ of an annulus in $S_k$ is a region bounded by two concentric $(k-1)$-dimensional spheres in $\mathbb{R}^{k-1}$.

Lemma 2 If $X = (x_1, \ldots, x_k) \in S_k$ and $Y = (y_1, \ldots, y_k) \in S_k$ belong to the same annulus of $C^A$, then

$$||f'(X) - f'(Y)||^2 \leq ||X - Y||^2.$$

If, additionally, $\xi_i = \sin(i\sqrt{d})$, $x_k, y_k \leq 1/\sqrt{2}$, and $||f'(X) - f'(Y)|| \leq d$, then

$$||X - Y||^2 - 3d^2/2 + O(d^2) \leq ||f'(X) - f'(Y)||^2.$$

Proof: Omitted.

Note that if $\xi_i = 1/\sqrt{2}$ for some $i$, then Lemma 2 also holds when $f'$ is replaced by $f$.

Corollary 1 If $\Lambda$ is a sphere packing with minimum distance $d$, then the minimum distance of the wrapped spherical code $C^A$ is also $d$.

Proof: If distinct $X, Y \in C^A$ belong to the same annulus, then $||X - Y|| \geq ||f(X) - f(Y)||^2 \geq d$, since the minimum distance of $\Lambda$ is $d$. If $X$ and $Y$ belong to different annuli, then the definition of $B$ guarantees their separation is $d$.

3.2 Asymptotic density of the wrapped spherical code

Let $\{\xi_i^{(d)}\}$ be the partition of $[0, 1/\sqrt{2}]$ used in the definition of a wrapped spherical code $C^A$ that has minimum distance $d$. Let $\phi_i = \sin^{-1}\xi_i^{(d)} - \sin^{-1}\xi_i^{(d)}$ denote the angular separation of the $i$th annulus. We show that if the maximum angular separation between annuli, $\phi \equiv \max \phi_i$ approaches 0 as $d \to 0$ and the minimum angular separation $\phi \equiv \min \phi_i$ does not approach zero too quickly, then the density of the wrapped code approaches the density of $\Lambda$. 

293
Theorem 1 Let $\Lambda$ be a $(k-1)$-dimensional sphere packing with minimum distance $d$. Let $C^\Lambda$ be a wrapped spherical code with respect to $\Lambda$ and with latitudes $\xi_1, \ldots, \xi_N$. If the maximum and minimum annulus angular separations satisfy $\lim_{d \to 0} \phi + (d/\phi) = 0$, then the asymptotic density of $C^\Lambda$ approaches the density of $\Lambda$, i.e., $\lim_{d \to 0} \Delta_{C^\Lambda} = \Delta_{\Lambda}$.

Proof: Omitted.

One line in the proof implies the following corollary.

Corollary 2 Let $\Lambda$ be a $(k-1)$-dimensional sphere packing with minimum distance $d$, and let $C^\Lambda$ be a wrapped spherical code with respect to $\Lambda$ and with latitudes given by $\xi_i = \sin \left( i \sqrt{d} \right)$ for $0 \leq i \leq \pi/(2\sqrt{d})$. Then the spherical code density satisfies $|\Delta_{C^\Lambda} - \Delta_{\Lambda}| \leq O(\sqrt{d})$.

3.3 Decoding wrapped spherical codes

An important question in channel decoding and quantization encoding is how to efficiently find the nearest codepoint to an arbitrary point in $\mathbb{R}^k$ (see, e.g., [18]). Often, an advantage of a structured code is that codepoints themselves need not be stored explicitly.

If the $k$-dimensional signal $X \in C^\Lambda$ is sent across an additive white Gaussian noise (AWGN) channel, then the received signal is $R = X + N$, where $N$ is a zero-mean Gaussian random vector with variance $\sigma^2$. The maximum likelihood decoder is a minimum distance decoder, i.e., given $R$, the decoder output is $\hat{X} = \arg\min_{X \in C^\Lambda} ||X - R||$, the closest codepoint to $R$. For any $R \in \mathbb{R}^k$ and any spherical code $C(k, d)$, the nearest codepoint of $C(k, d)$ to $R$ is the same as the nearest codepoint of $C(k, d)$ to $R/\|R\|$. Hence, in the following, we assume $R \in S_k$.

We now evaluate the performance of an efficient suboptimal decoding method. Given a received vector $R \in S_k$, let the decoder output be

$$\hat{X} = \arg\min_{X \in C^\Lambda} \|f(X) - f(R)\|.$$ 

Note that $X \in C^\Lambda$ implies $f(X) \in \Lambda$. Let $Y$ be a nearest neighbor of $f(R)$ in $\Lambda$. There is at most one candidate in the set $f^{-1}(Y)$ which could be a nearest neighbor to $R$, namely, the element $E$ which is in the same annulus as $R$. However, because of the buffer region $B$, $E$ might not be in $C^\Lambda$. This happens with probability $O(\sqrt{d})$ or less, for $B$ covers $O(\sqrt{d})$ of the sphere. (Such an $E$ exists provided $\|Y\| \leq 1$ and $R$ is not within $d$ of the border of an annulus, which holds with probability $1 - O(\sqrt{d})$.)

Thus, with probability $1 - O(\sqrt{d})$,

$$\hat{X} \in f^{-1}\left( \arg\min_{Y \in \Lambda} \|Y - f(R)\| \right),$$

which involves only $f$, $f^{-1}$, and the decoding algorithm for $\Lambda$.

It is known that when points from the packing $\Lambda$ with minimum distance $d$ are used on an AWGN channel, the probability of symbol error is $\tau Q(\frac{d}{\sigma})$ (see, e.g., [20]), where $\tau$ is the average number of codepoints at distance $2d$ from a codepoint and where $Q$ is the complementary error function defined by $Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt$.

The following theorem shows that the performance of efficiently decoding $C^\Lambda$ is asymptotically close to the performance of $\Lambda$.

Theorem 2 Let $\Lambda$ be a $(k-1)$-dimensional packing with minimum distance $d$, and let $C^\Lambda$ be a wrapped spherical code with respect to $\Lambda$ and with latitudes $\xi_i = \sin(i\sqrt{d})$. Let $P_e$ be the probability of symbol error when $C^\Lambda$ is used on an AWGN channel with equiprobable inputs and the decoder output is $\hat{X} = \arg\min_{X \in C^\Lambda} \|f(X) - f(R)\|$. Then

$$P_e \leq \tau Q\left( \frac{d}{2\sigma} (1 - O(d^{-1/4})) \right).$$

Proof: Omitted.

4 Conclusions

A new technique was presented that constructs wrapped spherical codes in any dimension and with any minimum distance. The construction is performed by defining a map from $\mathbb{R}^{k-1}$ to $S_k$. Although any set of points in $\mathbb{R}^{k-1}$ may be wrapped to $S_k$ using our technique, if the densest packing in $\mathbb{R}^{k-1}$ is used the wrapped spherical codes are asymptotically optimal, in the sense that the ratio of the minimum distance of the constructed code to the upper bound approaches one as the number of codepoints increases. This demonstrates the tightness of the upper bound in [7], asymptotically, and that previous lower bounds are not asymptotically optimal.

Acknowledgements: The authors thank N. J. A. Sloane for pointing out some of the best spherical codes in three dimensions for codes up to 33,002 codepoints, and to A. Vardy for helpful discussions.
